Summer Research:
Hypervelocity Globular Cluster

Sean Lewis

Simulation Parameters

- Input:
  - ▶ Blackholes: Mass ratio (1:100, 1:20, 1:10, 1:3), separation (1.7, 3, 5) parsecs
  - ▶ Globular Cluster: Closest approach (1.5, 2, 2.5, 3) times BH separation
- For each combination of operational parameters, cycle through initial blackhole phases 0 to 2pi
- Output:
  - ▶ Velocity of ejected GC, maximum tidal acceleration experienced, all operational params.

How BH phase affects ejection velocity

- Two humps corresponding to each BH being in-phase with passing GC.
- Globular cluster becomes captured when pi/2 out of phase with blackholes.
- Seems good, can pick out specific BH starting locations that produce maximum velocity.
- Issue: this analysis must be repeated with any change in input parameter.
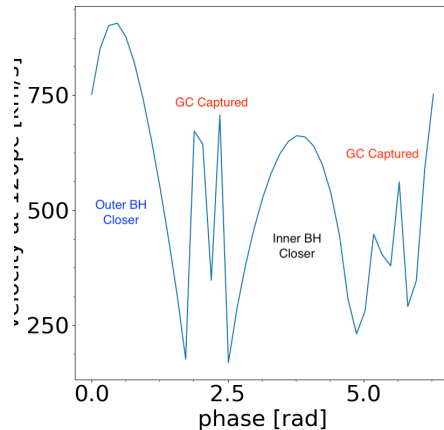

Backup Slides

3:1 Mass ratio

- 2-3 pc pass from larger BH.
- Tidal radius of 0.3-0.4 pc
